

## Interpreting Urine Drug Tests (UDT)

### Why a UDT is Important

- In an emergent situation, the immediate value of a UDT may be limited. However, some medications and illicit drugs are only present in urine for a brief time. Early collection (with child/youth consent) can be helpful for ongoing treatment planning and interventions post-acute stabilization including withdrawal management.
- UDT results can support harm reduction education with a child/youth by providing feedback about their substance use and potentially toxic substance supply. Youth may be surprised to learn that the substance they thought they were ingesting was something else.

### Considerations for Interpreting UDT

- It is important to understand timelines for detection, what other medication(s) have been prescribed (e.g., psychostimulants, benzodiazepines), and risks of false positive or false negative results.
- Initial UDTs use immunoassay that are quick but less accurate. Immunoassays may not distinguish between or detect all members within a single class of medications and may not detect synthetic/semi-synthetic substances.
- Urine collected can be used for confirmatory testing by liquid chromatography or gas chromatography–mass spectrometry (GCMS). This testing is highly sensitive and specific, but takes longer, and may need to be sent away.

### Timelines for detection of substances in UDT <sup>1</sup>

|                             | Substance                           | Length of time substance detected in urine after ingestion |
|-----------------------------|-------------------------------------|--|
| Depressants<br>(Downers)    | Alcohol                             | 6-8 hours  |
|                             | <b>Opioids</b>                      |  |
|                             | Buprenorphine                       | up to 7 days   |
|                             | Codeine                             | 2-5 days   |
|                             | Fentanyl – short term use           | 2-3 days   |
|                             | Fentanyl – chronic use <sup>2</sup> | Up to 4 weeks  |
|                             | Heroin metabolite (6-MAM)           | < 1 day  |
|                             | Hydromorphone                       | Up to 3 days   |
|                             | Methadone                           | < 6 days   |
|                             | Morphine                            | 2-5 days   |
|                             | Oxycodone                           | 2-4 days   |
|                             | <b>Benzodiazepines</b>              |  |
|                             | Short acting (e.g., lorazepam)      | 1-2 days   |
|                             | Long acting (e.g., diazepam)        | Up to 30 days (regular use)                                |
|                             | <b>Sedative Hypnotics</b>           |  |
| Gamma hydroxybutyrate / GHB | 12 hours                            |  |
| Zolpidem                    | 1-2 days                            |  |
| Stimulants<br>(Uppers)      | Amphetamines                        | 2-5 days   |
|                             | Cocaine                             | 2-3 days   |
|                             | Methamphetamine                     | 2-5 days   |
| Psychedelics                | Ketamine                            | Up to 14 days  |
|                             | LSD metabolites                     | Up to 4 days   |
|                             | Phencyclidine (PCP)                 | 5-6 days   |
| Cannabinoids                | Cannabis                            | Single use: 1-3 days      Chronic use ≤ 30 days            |

<sup>2</sup> Fentanyl persists in urine for up to 4 weeks due to lipophilic properties, not due to duration of action (i.e., fentanyl is not a long acting opioid)

### Possible causes of false positive and false negative results in urine drug testing

Clinicians should not automatically assume a false-positive or false-negative result if the patient is prescribed one of the medications listed below. This cross-reactivity table does not provide definitive answers as to the reason for a positive or negative UDT result. Clinicians are advised to request confirmatory testing if there is an unexpected result.

|                         |   |  |  |  |
|-------------------------|---|--|--|--|
| Opioids                 | False-negative results  | False-negative results can occur when immunoassays do not reliably detect the following semi-synthetic or synthetic opioids:   |  |  |
|                         |   | Oxycodone<br>Hydromorphone   | Buprenorphine<br>Fentanyl  | Methadone<br>Meperidine  |
|                         | False-positive results  | Cross-reactivity and false-positive results can occur with compounds that have a similar chemical and physical structure.  |  |  |
|                         |   | <b>Substances</b>  |  | <b>Cross reacts with:</b>  |
|                         |   | Fluoroquinolones<br>Poppy seeds<br>Dextromethorphan<br>Diphenhydramine<br>Quinine<br>Rifampin  |  | Morphine<br>Codeine<br>Heroin metabolite   |
|                         |   | Trazodone<br>Risperidone<br>Paliperidone   |  | Fentanyl   |
| Quetiapine<br>Verapamil |   | Methadone metabolite   |  |  |
| Benzodiazepines         | False-negative results  | Some benzodiazepines have distinct metabolic pathways and may not adequately cross-react on immunoassays (resulting in false negative). "Z-drugs" are not detected in benzodiazepine immunoassay panels. |  |  |
|                         |   | Lorazepam<br>Clonazepam  | Alprazolam<br>Zopiclone  | Zolpidem   |
|                         | False-positive results  | Cross-reactivity and false-positive results can occur with compounds that have a similar chemical and physical structure.  |  |  |
|                         |   | Sertraline   | Oxaprozin  |  |
| Amphetamines            | False-negative results  | Not applicable   |  |  |
|                         | False-positive results  | Amphetamines have the highest degree of cross-reactivity of any substance and thus the highest rate of false-positive results  |  |  |
|                         |   | <b>Substances</b>  |  |  |
|                         |   | Amantadine<br>Aripiprazole<br>Bupropion<br>Chlorpromazine<br>Clobenzorex<br>Desipramine<br>Ephedrine   | Fenproporex<br>Fluoxetine<br>L-Methamphetamine<br>Labetalol<br>Methylphenidate<br>Phentermine<br>Phenylephrine | Phenylpropanolamine<br>Promethazine<br>Pseudoephedrine<br>Ranitidine<br>Thioridazine<br>Trazodone<br>Venlafaxine |
|                         | Lactate dehydrogenase and lactate, in patients with lactic acidosis   |  |  |  |
| Cannabinoids            | False-negative results  | Synthetic cannabinoids very unlikely to cross-react. Typically present at very low concentrations.   |  |  |
|                         |   | Nabilone   |  |  |
| False-positive results  | Cross-reactivity and false-positive results can occur with compounds that contain THC or cannabidiol, or compounds that have similar chemical/physical structure. |  |  |  |
|                         | Sativex<br>Dronabinol   | Efavirenz<br>NSAIDs  | Proton pump inhibitors<br>Topical use of baby soap or shampoo  |  |
